

1) What is a Calculated Field in Tableau? How is it different from a regular field?

Ans:

A Calculated Field in Tableau is a new field created using a formula or expression based on existing data fields, functions, and operators.

Difference:

- **Regular field:** Comes directly from the original data source, such as Sales, Profit, or Region.
- **Calculated field:** Created by the Tableau user using a formula based on existing fields.

2) Difference between Row-Level and Aggregate-Level Calculations

Row-Level Calculation:

The calculation is performed for each individual row of data.

Aggregate-Level Calculation:

The calculation is performed after aggregating the data, such as using SUM, AVG, MIN, or MAX.

Key difference:

Row-Level	Aggregate-Level
Works on individual records	Works on aggregated values
Calculated before aggregation	Calculated after aggregation

3)How does Tableau handle NULL values in calculated fields?

A NULL value represents missing or unknown data. Tableau generally returns NULL when a calculation involves a NULL value, depending on the calculation.

If [Discount] is NULL, the result can also be NULL.

You can handle NULL values using functions such as IFNULL() or ZN().
