

1) What is a Parameter in Tableau and how does it differ from a Filter?

Ans:

A Parameter in Tableau is a user-defined variable that allows users to input or select a value that can control calculations, filters, reference lines, or other aspects of a visualization.

Difference:

- **Parameter:** Independent of the data and allows users to enter/select a value manually.
- **Filter:** Directly filters the data based on values present in a field.

2) Three use cases where Parameters are preferred over Filters.

Ans:

1. **Dynamic calculations** – Allow users to change values used in calculations, such as profit margins or sales targets.
2. **Selecting different measures** – Let users switch between Sales, Profit, Quantity, etc., in the same visualization.
3. **Dynamic reference lines or thresholds** – Allow users to change a benchmark or target value interactively.

3) Four data types supported in Tableau Parameters.

Ans:

The four main data types are:

1. **Integer**
2. **Float**
3. **String**
4. **Date/Time**
