

1. Difference between Live Connection and Extract Connection.

Live Connection	Extract Connection
Connects directly to the original data source.	Creates a saved snapshot/copy of the data.
Data can reflect the latest changes in the source when queried.	Data must be refreshed to include changes from the source.
Depends more on the performance of the original database.	Usually provides faster dashboard performance.
Requires access to the data source when using the workbook.	Can reduce the load on the original database.
Suitable for real-time or frequently changing data.	Suitable for faster analysis and large datasets.

Simple example:

- Live: Tableau directly asks the database for the latest data.
- Extract: Tableau works with a saved copy of the data.

2. Difference between Data Blending and Joining in Tableau?

Joining	Data Blending
Combines tables at the row level.	Combines data at the aggregated level.
Usually works within the same data source/connection environment.	Can combine data from different data sources.
Uses join types such as Inner, Left, Right, Full Outer.	Uses a primary and secondary data source.
Tables are combined before visualization/analysis.	Data sources remain separate and are combined during analysis.

Example: Joining Customer and Orders tables using Customer ID.	Example: Combining Sales data from Excel with Target data from another source using Month.
